“EXPLORING THE FUNDAMENTAL AND SIGNIFICANCE OF PROGRAMMING: A JOURNEY INTO THE DIGITAL WORLD”

When we arrived in this world, our parents taught us a language composed of millions of different words to convey our thoughts. Just like a Computer, they can only understand machine language code/binary numbers which are the series numbers’ of 1’s and 0’s, this series of binary numbers is fed and only interpreted by the computer, therefore, in order to talk to a computer just like what we must first translate our English instruction to Binary, the problem is it would be entirely feasible to convert every programming instruction we have to binary, just like our languages it is also composed of millions to billions of numbers. This is where “**PROGRAMMING**” comes into play as this is related to the development and implementation of instructions for computer programs so the computer/machine can perform specific tasks, solve problems, and support human interactions. This Programming is sort of an interpreter that can take instructions which is the input language and translate them into a specific language that the computer would understand which the output language is. Each languages is unique in how they operate. Programming is the process related to the development and implementation of instructions for computer programs so the computer can perform specific tasks, solve problems, and support human interactions.

This is where Programming started to be recognizable around the world, as it developed more languages to be instructed to a computer, As a result, computers/machines are able to absorb different instructions to understand humankind's demands and needs making Technology wider. In recent decades, computer programming has been a crucial factor in the progress of modern computing and the current information age. This advancement has enabled us to develop innovative software and systems that simplify various aspects of our daily lives. Programming offers benefits that go beyond the business world and extend to areas like education, healthcare, and entertainment. It plays a crucial role in our daily lives, making things easier and more efficient. Programming has revolutionized the way we learn, work, travel, and shop. It has enabled us to conduct research, find and analyze data results easily and accurately, design new products and services (data protection), manage our finances, and communicate with people all over the world. The pandemic has been significantly mitigated, thanks to the pivotal role played by digital technologies. Without programming and computers, Technology would not have progressed as much as it has, and we would not have access to online banking, e-commerce, and other conveniences like online shopping and doorstep delivery without computers and programming.

New opportunities and new challenges are opening up as programming embarks on more progressive technology in the future digital world, This new technology might incorporate and diversify more knowledge interfaces than humans can have, and automation and robotics be taking the form of future facilitating traditional industries, and management in every sectors. The computer has gone through many advanced processes, and this will not make humans belittled, but we should always remember these Program technologies are all just tools for making brilliant things, just like we humans are able to make, as we have the basic attitude of understanding and interpreting computers and computers have the capacity to do its best to also meet the urge and necessity of us, humans.
